Cardiovascular Introduction

The essential components of the human cardiovascular system are the heart, blood and blood vessels. It is a closed circulation pipe in which the blood flows, supplying oxygen, various nutrients, hormones, etc. to organs and tissues, and transporting the waste of tissue metabolism to the excretory organs, so as to maintain the homeostasis of the body's internal environment, the progress of metabolism and maintain normal life activities.

The cardiovascular system includes the pulmonary circulation, the systemic circulation, and the coronary circulation. The pulmonary circulation is part of the cardiovascular system which transports oxygen-depleted blood away from the heart, to the lungs, and returns oxygenated blood back to the heart. The systemic circulation is part of the cardiovascular system which transports oxygenated blood away from the heart, to the rest of the body, and returns oxygen-depleted blood back to the heart. Coronary circulation is another part of the cardiovascular system which refers to the movement of blood through the tissues of the heart. The coronary arteries refer to vessels that deliver oxygen-rich blood to the myocardium, while the coronary veins refer to vessels that remove the deoxygenated blood from

the heart muscle. The coronary arteries are classified as "end circulation", since they represent the only source of blood supply to the myocardium.

Cardiovascular diseases refer to a group of diseases involving the heart and blood vessels (arteries and veins), including atherosclerosis, arrhythmia, cardiomyopathy, heart failure, hypertension, coronary artery disease, coagulation disorders, etc. Elabscience® provides high quality ELISA kits to study multiple aspects of the cardiovascular system, including angiogenesis, blood pressure regulation, cholesterol metabolism, atherosclerosis, and more.

Company Brief Introduction

About Elabscience®

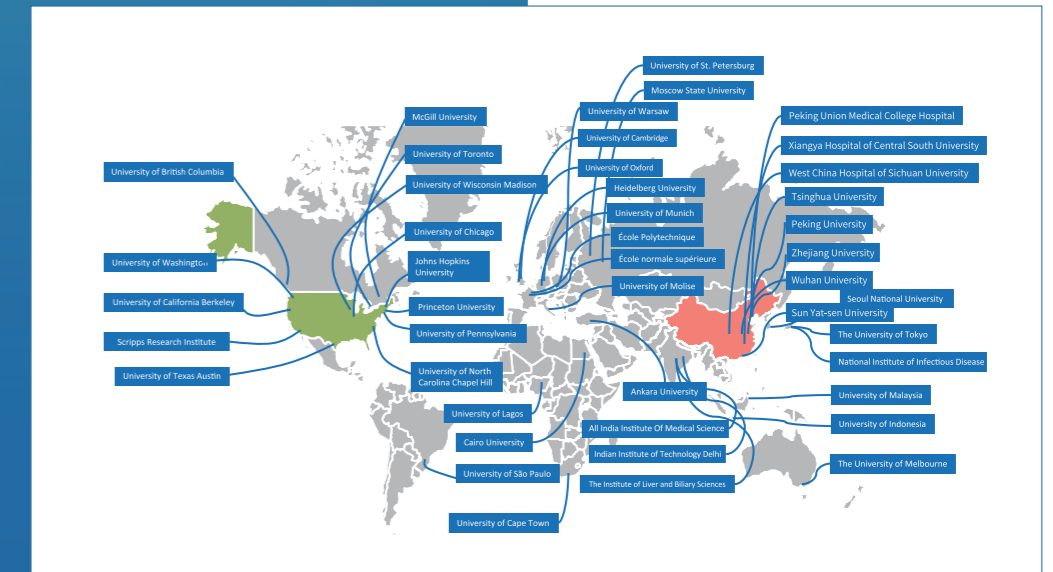

Elabscience® is a high-tech biological company specializing in the development, production and sales of immunoassay reagents. The main products are **ELISA Kits**,

CLIA Kits, FCM Antibodies, Cell Function Assays, Metabolism Assay Kits, Antibodies, Proteins, Labeling Kits, Immunology Related Reagents, etc.

Customer Distribution

The customers are distributed in more than **150 countries** on **5 continents**, basically covering all famous universities and research institutions in the world.

-  **59** Invention patents
-  **12000+** SCI articles
-  **208** Utility model patents

Why Choose Elabscience® ELISA Kits?

Strict Quality Control

- 8 processes for strict quality control
- Superior performance guarantees

Recommended by CiteAb

- Elabscience® was highly commended as "ELISA KIT SUPPLIER TO WATCH IN 2019" by CiteAb.

Supported by 12000+ SCI Literature

- Elabscience® products have been cited in more than 12,000 SCI papers, and published in *Nature Medicine*, *Nature*, *Cell*, *Immunity*, *Molecular Cancer* and other internationally renowned journals.

ELISA Kits Features

- ✓ High precision: Both inter and intra CV are <10%
- ✓ High sensitivity: Pg level
- ✓ Good specificity: Cross-reactivity <10%
- ✓ High precision over thousands of items: Covering various targets and species
- ✓ Flexible choices on size: 48T/96T/96T*5/96T*10
- ✓ One-step method available

Cardiovascular Research

01 Angiogenesis

Angiogenesis is the formation and remodelling of new blood vessels and capillaries from growth of pre-existing blood vessels. It mainly includes: a. Degradation of vascular basement membrane during activation; b. Activation, proliferation and migration of vascular endothelial cells; c. Reconstruction and formation of new blood vessels and blood vessel networks.

Angiogenesis is an important process of embryo growth and development, wound healing, granulation tissue formation and tumor occurrence and development, which involves the participation of various cells and molecules. It relies on extensive signal transduction networks between and within endothelial cells (ECs), their associated perietal cells (vascular smooth muscle cells and percutaneous cells), and other cell types (such as immune cells). The types of angiogenesis mainly include blastogenesis, non-blastogenesis and insertion.

02 Atherosclerosis

Atherosclerosis is a progressive disease of the vasculature that is a common underlying pathology in stroke and heart attack. It is characterized by chronic inflammation, oxidative stress, and lipid accumulation within the vessel wall. In atherosclerotic lesions, macrophages engulf large amounts of oxidized low-density lipoprotein (LDL) and transform into foam cells. Excessive proliferation and abnormal smooth muscle cells deposit proteoglycans around plaques, leading to calcification of blood vessel walls and arteriosclerosis. As the disease progresses, the fibrous cap on the surface of the plaque ruptures and forms a thrombus, which causes a blockage of the artery lumen, leading to an organ infarction. Risk factors for the development of atherosclerosis include high-fat diet, high blood pressure, diabetes, smoking, advanced age, and genetic mutations in key molecules.

03 Blood Pressure Regulation

Blood Pressure (BP) is the pressure of circulating blood against the walls of blood vessels. It is the power that pushes blood to flow through blood vessels. In different blood vessels are called arterial blood pressure, capillary blood pressure and venous blood pressure respectively, usually referred to as blood pressure refers to the arterial blood pressure of the systemic circulation.

Blood Pressure is influenced by cardiac output, systemic vascular resistance and arterial stiffness and varies depending on situation, emotional state, activity, and relative health/disease states. In the short term, blood pressure is regulated by baroreceptors which act via the brain to influence the nervous and the endocrine systems. Keeping blood pressure relatively constant and adjusting blood flow according to the needs of tissues and organs on these basis are the two necessary conditions for the cardiovascular system to protect the organs and tissues from adequate blood supply.

Improper regulation of blood pressure can cause hypertension or hypotension. Persistent hypertension is one of the risk factors for strokes, heart attacks, heart failure, and arterial aneurysms, and is the leading cause of chronic kidney failure. Blood pressure that is too low is known as hypotension. This is a medical concern if it causes signs or symptoms, such as dizziness, fainting, or in extreme cases, circulatory shock.

04 Coagulation

Coagulation refers to the process of blood changing from liquid to gel to form clots, which is an important link of hemostasis. The mechanism of coagulation involves activation, adhesion and aggregation of platelets, as well as deposition and maturation of fibrin.

When the vascular endothelium is damaged, blood exposure to the inner subcutaneous space triggers both primary and secondary hemostasis. Primary hemostasis refers to changes in platelets after injury. Exposure of endo-subcutaneous tissue factors to plasma factor VIII leads to the formation of cross-linked fibrin, and platelets immediately form embolism at the injured site. Secondary hemostasis occurs when factors other than plasma factor VIII cascade together to form fibrin chains that reinforce platelet embolism.

Coagulation disorder is a disease condition that can lead to bleeding, bruising or thrombosis, which is an important factor in the pathogenesis of atherosclerosis (AS) and coronary heart disease (CHD).

05 Cardiovascular Markers

Cardiac stem cells are thought to be a quiescent, heart-resident population that can reenter the cell cycle following injuries such as acute myocardial infarction. Cardiac stem cells isolated from the myocardium have self-renewal capabilities in vitro and the ability to differentiate in vivo into all three major cardiac cell types: cardiomyocytes, vascular smooth muscle cells, and endothelial cells. These cells play key roles in circulation, maintenance and support of cardiovascular activity, perfusion, and phylogeny. Analysis and identification of abnormal cardiac cell function and cardiac stem cell biomarkers are very important for screening, differential diagnosis, risk stratification, treatment and prognosis and follow-up evaluation of cardiovascular diseases.

In recent years, more than 300 markers of cardiovascular diseases have been discovered. At present, according to the main categories of cardiovascular pathology, clinical biomarkers of cardiovascular disease can be roughly divided into 11 categories: myocardial injury, cardiac load, myocardial fibrosis, inflammatory mediators, neuroendocrine hormones, myocardial remodeling, renal function injury, blood lipid, coagulation and fibrinolytic activity related biomarkers.

06 Lipid/Cholesterol Metabolism

Cholesterol is a sterol molecule and an essential structural component of animal cell membranes (approximately 30%), which is essential for maintaining membranes, regulating membrane fluidity, and establishing membrane permeability. Cholesterol is also a precursor to anabolic steroids, bile acids and vitamin D. Various hormones released by the adrenal cortex and gonadal glands of the human body, such as cortisol, aldosterone, testosterone, estradiol are steroid hormones.

Cholesterol is produced throughout the body and absorbed from the diet, with the liver, bones and spinal cord having the highest levels. Since cholesterol is insoluble in the blood, it is transported throughout the body via low-density lipoprotein (LDL) and high-density lipoprotein (HDL). Once inside the cell, cholesterol is transported via fatty acid binding proteins (FABPs). HDL acts as a scavenger by removing cholesterol from the walls of blood vessels and transporting it to the liver. Low density lipoprotein cholesterol (LDL-C) is a key causative factor in atherosclerosis and cardiovascular diseases, and is also a prime target for lipid-lowering intervention.

The vascular endothelium is comprised of monolayer of endothelial cells (EC) that line blood vessels and lymphatic vessels. Endothelial cells form a barrier between blood vessels and tissues and mediate the uptake of circulating nutrients, responding to endocrine hormones, angiogenic factors and neurotransmitters.

Endothelial cells are involved in many aspects of blood vessel function, including:

- Blood clotting (thrombosis and fibrinolysis).** Endothelial cells contain and express substances that block clotting, including heparan sulfate, which acts as a co-factor in activating antithrombin, a protease that inactivates several factors in the clotting cascade.
- Inflammation and swelling.** Endothelial cells actively signal the white blood cells of the immune system during inflammation.
- Angiogenesis.** The process of angiogenesis is regulated by pro-angiogenic and anti-angiogenic signals, activating signal molecules that bind to surface receptors of vascular endothelial cells to activate endothelial cells to release proteases, leading to basement membrane degradation. Endothelial cells then dissociate from the existing blood vessels and begin to proliferate, forming an extension to the source of angiogenic stimulus.
- Blood vessels constrict and dilate to control blood pressure.**
- Atherosclerosis and heart disease.** The vascular endothelium becomes dysfunctional following injury or in chronic inflammatory diseases such as atherosclerosis, diabetes, and cancer. In these settings, EC exhibit dysregulated transendothelial permeability, production of vasorelaxant factors, and intracellular signalin.

08 Vascular Smooth Muscle

Vascular smooth muscle refers to the specific type of smooth muscle that exists in the wall of blood vessels and makes up the main part of it. Vascular smooth muscle is primarily innervated by the sympathetic nervous system through adrenergic receptors. There are three types of adrenergic receptors found in vascular smooth muscle: α_1 , α_2 , and β_2 . The primary endogenous agonist for these cell receptors is norepinephrine (NE). Agonists of α_1 and α_2 receptors in the vascular smooth muscle lead to vasoconstriction, but agonism of β_2 receptors causes vasodilation and low blood pressure.

Excessive proliferation of vascular smooth muscle cells contributes to the progression of pathological conditions, such as vascular inflammation, plaque formation, atherosclerosis, restenosis, and pulmonary hypertension. Recent studies have shown that the majority of cells within atherosclerotic plaque, the predominant cause of heart attack and stroke, are vascular smooth muscle cell derived.

MCP-1(Monocyte Chemotactic Protein 1)	E-EL-H6005/E-EL-M3001/E-EL-R0633/E-MSEL-M0012	Human/Mouse/Rat
MMP-1(Matrix Metalloproteinase 1)	E-EL-H6073/E-EL-M0779/E-EL-R0617/E-EL-RB0349	Human/Mouse/Rat/Rabbit
MMP-9(Matrix Metalloproteinase 9)	E-EL-H6075/E-EL-M3052/E-EL-R3021	Human/Mouse/Rat
NOS1/nNOS(Nitric Oxide Synthase 1, Neuronal)	E-EL-H0742/E-EL-R1438	Human/Rat
NOS2/iNOS(Nitric Oxide Synthase 2, Inducible)	E-EL-H0753/E-EL-M0696/E-EL-R0520	Human/Mouse/Rat
NOS3/eNOS(Nitric Oxide Synthase 3, Endothelial)	E-EL-H0755/E-EL-M0456/E-EL-R0367	Human/Mouse/Rat
NRP1(Neuropilin 1)	E-EL-H6164/E-EL-R3041	Human/Rat
ON(Osteonectin)	E-EL-H1351/E-EL-M0867	Human/Mouse
OPN(Osteopontin)	E-EL-H1347/E-EL-M3030/E-EL-R0702	Human/Mouse/Rat
PAI1(Plasminogen Activator Inhibitor 1)	E-EL-H2104/E-EL-M3041/E-EL-R3025	Human/Mouse/Rat
PECAM1/CD31(Platelet/Endothelial Cell Adhesion Molecule 1)	E-EL-H1640	Human
PGE2(Prostaglandin E2)	E-EL-0034	Universal
SOST(Sclerostin)	E-EL-H1544/E-EL-R3032	Human/Rat
ST/5-HT(Serotonin/5-Hydroxytryptamine)	E-EL-0033	Universal

Elabscience® ELISA Kits Citation

Elabscience® products have been cited in more than **12,000** SCI papers with a total impact factor of **55,000 +**, and have been published in top international journals such as *Nature Medicine*, *Nature*, *Cell*, *Immunity* and *Molecular Cancer* for many times.
